ELECTROPURE™ EDI MODULE INSTALLATION CHECKLIST

1. Safety
2. Handling the Module
3. Mounting Options
4. Module Orientation
5. Pipe and Tubing Connections
6. Power Connection & Wire Conventions
7. Grounding
8. Torque
9. Module Startup

1. Safety

Please read and understand the Safety Section of the Electropure™ EDI OEM Technical Manual before installation. Please **train your colleagues** regarding the safe design and operation of EDI modules. Key safety topics are the use of electricity around water and the handling of the gases produced at the electrodes. Include a safety section in the customer site maintenance manual.

2. Handling the Module

The module is designed to be compact and lightweight. However, **do not lift by the plumbing or electrical connections**. Do not lift by the end covers. There are 4 lifting and 8 mounting points on the aluminum frames.

3. Mounting Options

Mount the modules so that the 19 face bolts are accessible for torqueing with a torque wrench.

The module can be mounted in different ways. The most popular way is to install L-or U- brackets on the skid, which provide a secure track for module to sit in. Alternately, the module may rest on a single, central rectangular rail. The module must then be secured at the top via two of the mounting holes on the top, either at the front or the back, but not both. See the “Mounting Methods” drawing in the Electropure™ EDI OEM Technical Manual.

Do not bolt both the front and rear of the module to fixed points as this can constrain and stress the module hardware during torqueing. One of the endplates needs to be able to move to allow unrestricted torqueing.

SnowPure, LLC • 130-A Calle Iglesia • San Clemente, CA 92672 USA • +1.949.240.2188 • www.snowpure.com

4. Module Orientation

Electropure™ EDI modules are designed to be installed in an upright, vertical position. In a horizontal position, gas can become trapped in the chambers and interfere with ion removal.

5. Pipe and Tubing Connections

The standard modules are provided with 1" female pipe thread fittings (US Standard FNPT) for the main feed and the product. Sanitary Quick-Disconnect connections are the Sanitary product option (this option comes with two 1" Sanitary Sani-tech™ flange fittings, complete with Buna-N seals, endcaps for sealing and protection, and clamps.

> *SnowPure recommends using the high strength filled-nylon clamps provided. Avoid using steel clamps which are designed for metal flanges. The clamps provided by SnowPure apply an even pressure around the circumference of the flange.*

Use Teflon® tape for sealing the threads. **Do not use normal pipe sealants made for metal threads as they often contains solvents that will weaken the plastic.** Even "FDA-approved" pipe sealants may contain these solvents. The use of such pipe sealant voids the SnowPure, LLC Limited Warranty. SnowPure can recommend/provide compatible pipe sealants.

It is very important that the threads are protected before installation to prevent damage and subsequent leaks. Secure the fittings with a tool to prevent twisting them during threading. If the fittings are not "backed up" during tightening, they may crack and need to be returned to the factory for repair.

Do not over-tighten the fittings. Starting with the first thread of the fitting, wrap pipe tape three full wraps, continuing over the length of the threads. Wrap Teflon™ thread tape in the direction of the threads overlapping each wrap by one-half the width of the tape. Screw the male fitting into the 1" female port (be sure to backup this fitting) on the module and tighten by hand. Using a strap wench only, tighten the connection an additional ½ to 1 full turn. Avoid over-tightening the fittings, as this may cause manifold or fitting damage. Read the full installation instructions accompanying the module.

The tube connections for the concentrate and electrode stream are 3/8" and 1/4" (see module drawing push-in-type, self-sealing (John Guest™) connections. The electrode outlet tubing is colored "yellow" and should be directed to waste.

There is a **metric conversion kit** available which converts the 3/8 inch and ¼ inch tube to metric tubing sizes (8 mm). Contact SnowPure for details and pricing.

6. Power Connection & Wire Conventions

The connection between the module and the power supply is a water-tight gold-plated, three-connector fitting. The module is provided with a keyed male fitting at the bottom of one face of the module. A 12 foot (4 meter) power cord, with female connector, is provided with each module. The GREEN (o), BLACK (-), and WHITE (+) wires at the end of the power cord should be connected to the appropriate terminals and ground of the regulated DC power supply.

The **(DC -) cathode** is always **BLACK**.
The **(DC +) anode** is **RED** (on older models it was WHITE).
The **Ground** is always **GREEN**.

7. Module and Water Stream Grounding

The module should be grounded in 3 distinct ways.

Primarily, the module is grounded through the green wire in the main DC electrical power connection. All conductive parts of the module are grounded together to the green wire of the connection. This should be grounded to a suitable ground by a qualified electrician. The system frame should be grounded to the same ground.

The module may also be physically grounded to the system frame via its mounting, providing the frame is properly grounded to a grounding grid or ground rod per local code. DO NOT GROUND TO WATER OR SPRINKLER PIPE.

Since the water streams are also conductive, current from the anode and cathode can flow through the various water streams looking for ground. It is good design to provide a “T” connection in various water streams, through which a conductive piece can be connected directly to ground (e.g., stainless steel rod with wire attached). Without grounding, the current in the water may cause metal pieces remote from the EDI system to present a high voltage, causing a safety concern and/or damage to instrumentation.

SnowPure, LLC • 130-A Calle Iglesia • San Clemente, CA 92672 USA • +1.949.240.2188 • www.snowpure.com

SnowPure recommends the following streams be thus grounded:

1. Feed between the module and any instrumentation or sensors in the RO permeate.
2. Concentrate outlet (most conductive stream).
3. Both the electrode inlet and outlet (these have the highest potential for transmitting voltage.

   NOTE: Do not ground the high resistivity EDI product stream. Byproducts from the electrochemistry may introduce undesirable trace iron or other metal ions into the product stream.

   NOTE: Electrical measuring devices like conductivity, resistivity, and pH probes can give erroneous readings if their streams either measure stray current/voltage or measure resistance to ground via the conductive piece.

8. SnowPure XL EDI Torque Specifications and Procedure

Torque is critical for the SnowPure EDI module. Continuing improvements in SnowPure materials and manufacturing processes require SnowPure to update Specifications and Procedures. It is important for maintaining internal pressure to achieve water quality, and for preventing internal and external leakage.

Check the torque at the following milestones/events and re-torque if necessary:

1. Initial installation - after the module has been mounted to the skid,
2. prior to start-up and after initial testing at customer site,
3. periodically (weekly) for the first month until all of the internal plastic parts have fully compressed,
4. once every quarter, and
5. if there is a decline in product water quality.

Prior to either checking or applying torque, make sure that all pressure to the SnowPure EDI module has been relieved. The torque should be set with NO INTERNAL WATER PRESSURE. Follow all safety rules and procedures as required.

Refer to the illustration and table below for the proper torque sequence and values. The procedure requires a 9/16-inch (14 mm) hex socket and a torque wrench.

Tighten the first eight (center) bolts in sequence and then measure the distance (X-distance) between the end plates near the four center bolts. Tighten the remaining 11 bolts, measuring between the plates as torque is applied, tighten only enough to keep an even distance between the plates. Care should be taken not to “over-torque´ the bolts, as this can crack or otherwise damage the end plates, especially on the corners. The end plates should be parallel and not bowed.

Recommended Torque Settings and Torque Sequence:

Module	Normal Torque
XL, -SR, -R	20 ft-lbs (27 N-m)
XL-HTS (all)	10 ft-lbs (13 N-m)

9. Module Startup Considerations

It is recommended the system piping be thoroughly flushed prior to installation.

The key to proper EDI startup is to run as little water through the modules as possible during the plumbing checkout before applying power. The more water and ions that enter the modules the longer the initial regeneration.

Make all mechanical, plumbing, and electrical connections.

Ensure that there is a filter just before the EDI system if the EDI is not connected directly to the RO permeate. This will prevent construction debris from entering the EDI modules, especially when the EDI system is fed from an intermediate RO permeate storage tank.

If the EDI is fed from a separate tank, the prefilter should be very fine (5 micron to 10 micron) to prevent silt from entering and fouling the modules.

Bleed all air out of plumbing system by first filling the manifold(s) and modules slowly with water, then “pulsing” water to all three streams to knock bubbles loose. The manifold(s) should be designed to have no dead legs that can trap air. Removing the air at startup is important because airlocks in only some of the modules will prevent all modules from getting the same flow of water. There may be bacteria in the modules after shipment and storage, which can be dislodged at this point. (Initial sanitization to come later.)

Check all plumbing connections for leaks, and repair if needed.

Have data sheets and startup notebook on hand. Record initial data and any observations. Call Technical Service at SnowPure with any questions.

Apply DC power as soon as possible. If too much water (with ions) is sent through the module(s) before power is supplied the excess ions will need to be removed with a longer regeneration procedure.

Check to be sure all three (3) streams for all modules are flowing at the recommended, design flows.

Check that the pressure drops of all three (3) streams are approximately correct.

SnowPure, LLC • 130-A Calle Iglesia • San Clemente, CA 92672 USA • +1.949.240.2188 • www.snowpure.com

Check all modules for startup current. The amperage may be higher than normal on startup and should drop to a nominal level within 1 hour. All modules should have similar currents to one another. If they are not similar this may mean that different modules have different concentrate flows and therefore different concentrate conductivities.

Check that the ion concentrations in the concentrate streams are all high. If the module(s) are running at 90% recovery, then the concentrate should have about 11 times the concentration of the feed. Perform a mass balance on the inlet and outlet ions to determine if the module(s) are regenerating (excess ions in outlet) or underpowered (too few ions in outlet).

Check all system permissions and interlocks. Check all flow and pressure sensors and switches to ensure that minimum flows are set properly and the correct signals are presented to the control system.

Product resistivity should rise to the design criteria within one hour of start-up. If excess ions were introduced during the startup procedure, then regeneration may be required before quality is achieved. Consult the O&M Manual for the proper regeneration procedure.

Check torque in the **unpressurized** state (with no pressure) and adjust. Follow up with the recommended torque procedure.

Perform a sanitization, especially if the site is for USP Purified Water. Consult the O&M Manual for the proper sanitization procedure.

Leave a maintenance manual and maintenance log at the site with the customer.
